---

The aim of this study was to investigate mortality trends in Novosibirsk in 1985–2008. The assessments of dynamics of total and cardiovascular mortality, tumor-induced mortality, and mortality from external causes (accident, suicide, violence) have been conducted. Gender-specific features of mortality and its structure as well as its levels in comparison with all-Russian parameters have been shown. Changes in all-cause mortality during 1985–2008 were caused mainly by changes of cardiovascular mortality and mortality from external causes, while cancer mortality has changed insignificantly, tending to decrease. In structure of all-cause mortality prevailed mortality due to cardiovascular disease. Its weight has increased in men and has not changed in women. The weight of cancer mortality in the structure of all-cause mortality has decreased in both men and women.
